(54) Screw rotor set.

(57) A screw rotor set for an air compressor or the like includes a male rotor (3) having helical lobes extending along its length and a female rotor (4) having helical recesses extending along its length. In use, the rotors (3,4) rotate about respective axes (1,2) and cooperate with the lobes being received in the recesses with a small clearance between them. Only one of the rotors (3 or 4) carries a coating (11) which is of heat-resistant material, has a coefficient of thermal expansion substantially the same as that of the said rotor (3 or 4) and has a hardness which is substantially different to that of the other uncoated rotor (4 or 3).

## SCREW ROTOR SET

The present invention relates to a screw rotor set as is used in an air compressor, fan, vacuum pump or the like.

A conventional set of rotors for a screw compressor, generally represented by reference numeral 5, is illustrated diagrammatically in perspective in Figure 1. This rotor set comprises male and female rotors 3 and 4 which are rotatable about respective parallel axes 1 and 2. The male rotor 3 is of generally clover-leaf cross-section and has three ridge portions or lobes 6 extending helically in the axial direction while the female rotor 4 has valley portions or recesses 7 extending helically in the axial direction and in mesh with the lobes 6. The lobes and recesses 6 and 7 are so designed and constructed that they engage one another in the manner of intermeshing gears to leave a small clearance between each lobe 6 and the corresponding recess 7.

When using the screw rotor set 5 in, for instance, an air compressor, the rotors 3 and 4 are rotated by drive means (not shown) in the direction indicated by the arrows to compress and feed the air in the valley portions 7 rearwardly in the axial direction, as indicated by the white arrow, within a casing (not shown) housing the elements 3 and 4.

Figure 2 is a front view of the screw rotor set 5 in which, as described above, a small clearance is defined in the region 8 between the rotors 3 and 4. A reduction of the clearance would improve the air compression efficiency, but would be disadvantageous in that the danger of contact between the elements 3 and 4 due to, for instance, thermal expansion is increased. In order to overcome this problem, it is known to coat the male and female elements 3 and 4 with a layer 9 of polytetrafluoroethylene (as sold under the Registered Trade Mark TEFLO) with a thickness of tens of microns, thereby reducing the clearance between the lobes and recesses. As a result, even if the elements 3 and 4 are caused to come into contact due to thermal expansion or the like, only the coatings 9 are removed or separated from the elements 3 and 4. Therefore, accidents such as breakdowns, due to thermal welding between the metallic elements 3 and 4 can be avoided.

When applying the coatings 9 to the elements 3 and 4 there is considerable difficulty in precisely setting the thickness of each coating 9, whereby the thickness of the coatings tends to vary. There is the further problem that the coatings 9, which are made from the same material, tend to weld together upon contact with each other and consequently the coatings 9 become substantially separated from the elements 3 and 4, resulting in

difficulty in defining the optimum clearance between the lobes and recesses of the elements 3 and 4.

It is thus an object of the present invention to provide a screw rotor set in which the rotors are substantially prevented from contacting one another and which can operate whilst defining an optimum clearance between the rotors.

According to the present invention a screw rotor set for an air compressor or the like including a male rotor having helical lobes extending along its length and a female rotor having helical recesses extending along its length, the rotors being adapted to cooperate in rotation with the lobes being received in the recesses with a clearance therebetween is characterised in that only one of the rotors carries a coating which is of heat-resistant material, has a coefficient of thermal expansion substantially the same as that of the said rotor and has a hardness which is substantially different to that of the other uncoated rotor.

It is preferred that the coating is machined subsequent to its application to the said rotor so that the two rotors cooperate in a precisely predefined manner, whereby the clearance between them can be more precisely predetermined.

The coating may comprise a material whose hardness is substantially less than that of the uncoated rotor and in this event if the two rotors should contact, in use, portions of the coating will be worn away so as to optimise the clearance between the two rotors. Alternatively, the coating may comprise a material whose hardness is substantially greater than that of the uncoated rotor and in this event portions of the uncoated rotor will be worn away if the two rotors should contact, in use. The precise value of the hardness of the coating is not important but what is important is that it is significantly different to that of the uncoated rotor.

As mentioned above, the coating is heat resistant to enable it to withstand the heat generated by the interaction of the rotors. Its coefficient of expansion is substantially the same as that of the coated rotor, though it will be appreciated that a small difference may be tolerated provided that this difference is sufficiently small that no damage occurs, in use, due to differential thermal expansion.

The invention also embraces a screw compressor or the like including a screw rotor set of the type referred to above.

Further features and details of the present invention will be apparent from the following description of one preferred embodiment which is given with reference to Figure 3 of the accompanying

drawings which is a front view of a screw rotor set in accordance with the present invention.

The same reference numerals are used to designate similar parts throughout the Figures.

The preferred embodiment of the screw rotor set, which is designated 10 in Figure 3, is substantially similar to the conventional screw rotor set shown in Figures 1 and 2 except that only one of the rotors 3 and 4, in this case the male rotor 3, is coated with polytetrafluoroethylene or the like, as indicated by the broken lines. This coating is preferably at least 100 microns thick and in practice is several hundreds of microns thick. After the coating has been applied it is machined with a high degree of accuracy to provide a machined coating 11 of precisely predetermined dimensions which permits the rotors 3 and 4 to engage with each other with an optimum clearance.

The machined coating 11 permits the metallic male and female rotors 3 and 4 to operate with an optimum clearance therebetween so that when they are rotated by drive means (not shown), they coact to compress the air with a high degree of efficiency.

In use, even if the elements 3 and 4 come into contact with each other due to thermal expansion or the like, only that portion of the coating 11 on the rotor 3 which is actually contacted is scraped off since the material of the coating 11 is less hard than that of the uncoated element 4, thereby naturally creating the optimum clearance. Thus the coating 11, whose thickness is also preferably at least 100 microns, more preferably several hundreds of microns, prevents contact of the elements 3 and 4.

It is to be noted that the female rotor 4 may carry the coating instead of the male rotor 3. In other words, either one of the rotors 3 and 4 may carry the coating.

Instead of polytetrafluoroethylene, other heat-resistant materials may be used, provided that their coefficient of thermal expansion is substantially the same as that of the rotor carrying the coating and their hardness is substantially different from that of the uncoated rotor. In order to apply the coating material onto a rotor, various coating techniques, such as metal-vapour plating, spray coating or the like, may be used.

It follows therefore that the present invention embraces a screw rotor set having a rotor carrying a coating or film of metal which is harder than the other uncoated rotor. In this case, in distinction to the preferred embodiment described above, any portion of the uncoated rotor which comes into contact with the coated rotor is scraped off to create or maintain the optimum clearance between the rotors 3 and 4.

In both cases, breakdown due to contact be-

tween the male and female rotors can be prevented and the screw rotor set can be operated with an optimum clearance between the lobes and recesses of the male and female rotors.

Since a coating is applied to only one of the rotors and the coating is preferably machined after application, setting or defining the clearance between the rotors is greatly facilitated and the set of screw rotors can be fabricated relatively inexpensively.

## Claims

- 5 1. A screw rotor set for an air compressor or the like including a male rotor having helical lobes extending along its length and a female rotor having helical recesses extending along its length, the rotors being adapted to cooperate in rotation with the lobes being received in the recesses with a small clearance therebetween, characterised in that only one of the rotors (3 or 4) carries a coating (11) which is of heat-resistant material, has a coefficient of thermal expansion substantially the same as that of the said rotor (3 or 4) and has a hardness which is substantially different to that of the other uncoated rotor (4 or 3).
- 10 2. A rotor set as claimed in claim 1 characterised in that the coating (11) is machined subsequent to its application to the said rotor (3 or 4).
- 15 3. A rotor set as claimed in claim 1 or claim 2 characterised in that the coating (11) comprises a material, such as polytetrafluoroethylene, whose hardness is substantially less than that of the uncoated rotor (4 or 3).
- 20 4. A rotor set as claimed in claim 1 or claim 2 characterised in that the coating (11) comprises a material, such as a metal, whose hardness is substantially greater than that of the uncoated rotor (4 or 3).
- 25 5. A rotor set as claimed in any one of the preceding claims characterised in that the thickness of the coating is at least 100 microns.
- 30 6. A screw compressor characterised by a screw rotor set as claimed in any one of the preceding claims.
